What is HIV?

HIV (Human Immunodeficiency Virus) attacks the immune system. Left untreated, it can lead to AIDS.

Causes

HIV is caused by infection through contact with certain body fluids from a person who has HIV.

How it spreads

- Unprotected sexual contact
- Sharing contaminated needles
- Mother-to-child transmission during pregnancy or breastfeeding
- Blood transfusion with infected blood

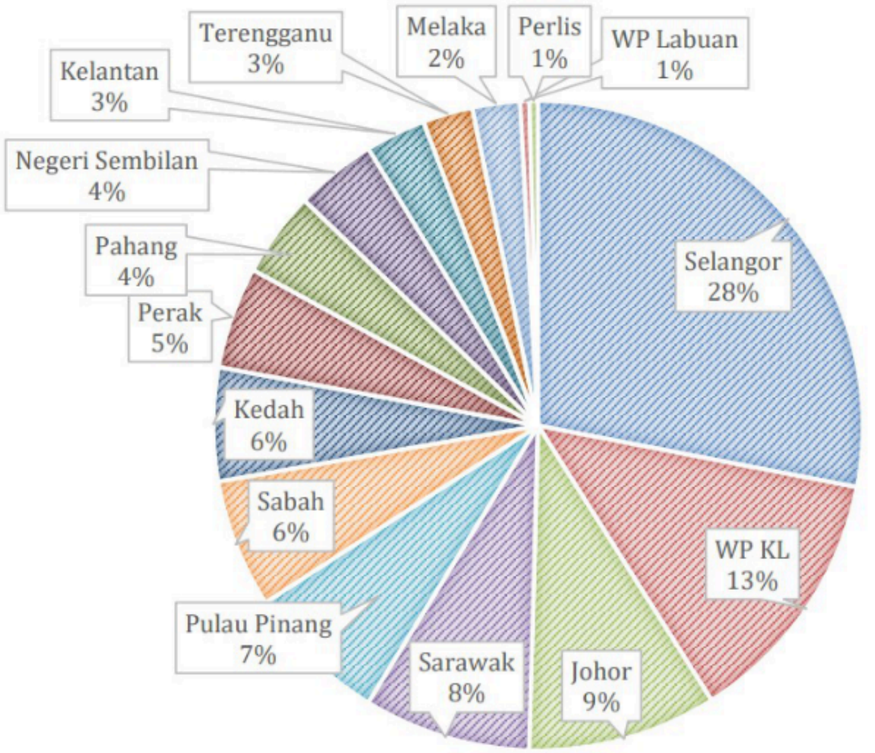

Effects

HIV weakens the immune system. With modern treatment, many people with HIV live long and healthy lives.

HIV Statistics

STATE	PEOPLE LIVING WITH HIV	NEW INFECTIONS (ANNUAL)
SELANGOR	26,000	1,062 (2023)
KUALA LUMPUR	12,000	357 (2023)
JOHOR	8,000	188 (2024)

Medication and Treatment

Antiretroviral Therapy (ART)

ART is the standard treatment for HIV. It reduces the viral load, improves immune function, and reduces transmission risk.

How it works

Reduces Viral Load: Suppresses replication of the HIV virus in the blood.
Restores Immune Function: Helps the body fight infections.
Prevents Transmission: Undetectable viral load = Untransmittable.

Access & Adherence

Regular treatment and clinic follow-ups are essential. Adherence is key to success.

Prevention

Practical Steps

- Use condoms consistently and correctly.
- Test regularly and know your status.
- Do not share needles; use clean equipment.
- Consider PrEP for high-risk individuals.
- Ensure blood is screened before transfusions.

Promote safe practices and supportive, non-stigmatizing messaging.
